ABSTRACT

Suppliers of Multinationals and the Forced Linkage Effect: Evidence from Firm Level Data^{*}

Using information on more than 1000 firms in a number of emerging countries, we find quantitative evidence that suppliers of multinationals that are pressured by their customers to reduce production costs or develop new products have higher productivity growth than other firms, including other host country suppliers of multinationals. These findings provide first empirical support for a “forced linkage effect” from supplying multinational companies. Our findings hold controlling for other factors within and outside the supplier-customer relationship and when endogeneity concerns are taken into consideration.

JEL Classification: F23, O12

Keywords: backward linkages, multinational customers, suppliers, forced linkage, productivity spillovers

NON-TECHNICAL SUMMARY

Empirical evidence shows that domestic firms increase productivity in the wake of an influx of foreign multinationals. This is generally interpreted as suggesting that there is learning from multinationals, whereby multinationals voluntarily share knowledge and cooperate with their suppliers. We argue that this is a somewhat overly benevolent view of how multinationals manage their suppliers in emerging economies. We suggest an alternative interpretation, namely that multinationals force their customers to adopt new practices – and may punish if these are not implemented to their satisfaction. Using a rich firm level data set for Central Europe and Central Asia, we find robust evidence that a domestic supplier to a multinational only experiences productivity gains if the supplier status is interacted with a variable indicating that there is pressure from customers. This shows that there is a “forced linkage” at work and that spillovers do not materialize in the absence of such pressure.

1. Introduction

The search for positive productivity effects (commonly termed “spillovers”) from multinational companies to host country firms has attracted considerable interest in the academic literature. While the earlier literature looked specifically for within-industry “horizontal spillovers”, the consensus is now that much stronger effects should be expected from vertical and in particular backward linkages between multinationals and their local suppliers.¹ Somewhat inspired by these empirical findings, many countries have attracted actively foreign direct investment (FDI) with fiscal incentives, hoping that in return indigenous suppliers will learn through their business relationship with multinational customers.²

While the available empirical literature produces encouraging results, it suffers from one main conceptual shortcoming. The traditional backward spillovers studies, such as Javorcik (2004), measure linkages between multinationals and domestic firms only at the industry level. Specifically, productivity in domestic firms is linked to a measure of the importance of multinationals in downstream industries, calculated using aggregate input-output tables. This does not allow the researcher to identify the exact channels through which domestic firms in upstream industries are expected to benefit – is it a supplier effect, a competition effect, or something else entirely?³

Javorcik and Spatareanu (2009) and Gorodnichenko et al. (2007) are among the first to confront this limitation. Javorcik and Spatareanu (2009) use firm level data for the

¹ The most widely cited example of a study on horizontal spillovers is probably Aitken and Harrison (1999), see also Haskel et al. (2007) and Keller and Yeaple (2009). The importance of backward linkages has been shown in theoretical models (Rodríguez-Clare, 1996; Markusen and Venables, 1999) as well as recent econometric studies (Javorcik, 2004; Liu, 2008, Girma et al., 2008). There are also studies that point to a potential for negative spillovers through backward linkages, due to potential hold up problems between supplier and multinational customer (e.g., Driffield et al., 2002; Blalock and Gertler, 2008). Görg and Greenaway (2004) and Havranek and Irsova (2012) provide comprehensive reviews of this literature.

² Harrison and Rodríguez-Clare (2009) argue that China's emphasis on domestic content requirement to foreign multinationals has been, *inter alia*, motivated by empirical evidence on productivity spillovers from foreign direct investment to supplying industries.

³ There are also methodological problems related to the assumptions implicit in the use of aggregate input-output tables, see Barrios et al. (2011) for a discussion.

Czech Republic, including information on whether a domestic firm is a supplier to a multinational. They show that suppliers are indeed more productive than non-suppliers. Gorodnichenko et al. (2007) use data for 17 Eastern European and Central Asian countries. They exploit firm level information on the share of output supplied by domestic firms to multinationals and find that a higher share is correlated with higher productivity growth. These papers, however, are silent on the actual mechanism that is at work and that causes productivity to increase. We, therefore, expand on these papers by examining one potential mechanism through which suppliers may improve their productivity. We refer to this as a “forced linkage effect”.

While many authors interpret the above results as suggesting that there is learning from multinationals, whereby multinationals voluntarily share knowledge and cooperate with their suppliers (backed up by some case study evidence, such as Moran, 2001), this may be a somewhat overly benevolent view of how multinationals manage their suppliers in emerging economies. An alternative interpretation is that multinationals force their customers to adopt new practices – and may punish if these are not implemented to their satisfaction. Blomström and Kokko (1998), also based on case study evidence, point out that such “forced linkage effects” may be an important mechanism through which domestic suppliers can improve their performance.

To our knowledge, no one has explored empirically the existence of such a “forced linkage” mechanism thus far. This paper attempts to fill this gap in the literature. We investigate empirically whether this is an important channel through which multinationals increase the productivity of their suppliers. In order to do so, we use a rich source of firm level data for emerging market economies in Central and Eastern Europe and Central Asia. This data comes from the Business Environment and Enterprise Performance Survey (BEEPS) provided jointly by the World Bank and the European Bank for Reconstruction and Development (EBRD). We use the 2005 survey, complemented with some information

from the 2002 survey. Our dataset provides unique information, at the firm level, on whether a firm supplies multinationals (and how much) and also on whether a firm perceives to be subject to pressure from customers to reduce production costs or to create new products. The combination of these two variables is central to our measurement of the forced linkage effect.

What exactly do we mean by a “forced linkage effect”? We conceptualize this idea in the following way. First, multinationals require that their suppliers meet their higher standards on product features, delivery schedules, quality control, inventory holding and accommodate continuously their demanding business procedures. Second, such requirements have a potential productivity enhancing effect on host country suppliers because multinationals have gathered their own experience and best practices with similar products in their main country. Third, and this is the main difference from a mere cooperation effect, suppliers are forced by their multinational customers to meet those requirements.⁴ Multinationals, due to their extensive experience with international production networks, are in a position to evaluate the performance of host country suppliers accurately. This enables them to “punish” local suppliers, e.g., through switching supplier sources or forcing price reductions, if the required standards are not met.

While the concept of a “forced linkage” is not firmly grounded in the existing theoretical literature, recent theoretical developments on imperfect contracts and bargaining may provide some guidance for a better understanding of frictions between customers and suppliers in general and the forced linkage effect in particular. In the “property rights” view of the firm, as applied to international sourcing decisions by, e.g. Antràs (2003) and Antràs and Helpman (2004, 2008), a final good producer and its one supplier are engaged in generalized Nash bargaining on the total surplus generated from the relationship. In this set up, one interpretation of “pressure” from the customer is that it shifts the bargaining

⁴ For example, Javorcik (2008) provides some evidence for the Czech Republic that multinationals require suppliers to improve quality assurance, acquire ISO 9000 certification or improve the timeliness of delivery.

weight in favor of the customer. Normally, we would expect that this would reduce the incentives for the independent supplier and thus lead to an underinvestment in terms of effort, i.e. lower productivity for the supplier.

However, the situation of a multinational company and its supplier is likely to be somewhat different than assumed in this stylized model. Firstly, the multinational has access to superior technology, which it may transfer to the supplier. This may either be done voluntarily, or it may come with pressure to fulfill some tough requirements or else be punished. The latter would correspond to our notion of a “forced linkage”. In our empirical analysis, we attempt to distinguish the simple technology transfer effect from a forced linkage effect. Another important difference from the theoretical model is that it is unlikely to be the case that one supplier exclusively supplies one multinational firm. Rather, independent suppliers have the option of working for additional customers.⁵ In this case, the benefits of responding to pressure by multinationals might have additional positive effects for the output sold to other firms. These two aspects are likely to overcome the disincentive to provide effort when pressured by the customer, and provide higher overall productivity gains when supplying pressuring multinationals.

Our paper is, to the best of our knowledge, the first to investigate whether knowledge is transferred through a forced linkage or through a more cooperative channel. Thereby we add to the existing studies on productivity spillovers from multinational companies, providing one further step towards understanding the mechanisms at work. Indeed, the existence of a forced linkage effect might help explain an ambivalence often found in surveys on suppliers of multinationals: they complain occasionally about their

⁵ Grossman and Helpman (2002) allow the produced good to be valuable for other producers on a secondary market in cases in which the bargaining breaks down. This offers a positive outside option for the supplier at the bargaining stage. Note that the commitment given by the multinational to keep the supplier as a separate legal entity (i.e., not to “integrate” the supplier) is that the customer gives up a valuable outside option at the bargaining stage (see Antras and Helpman, 2004). In Grossman and Helpman (2004) a customer can give its supplier a higher stake in the relationship when he cannot monitor its independent supplier. While this creates incentive for the supplier to provide more effort, it might also as well bind the supplier to this specific customer when the supplier uses its option to serve other customers.

multinational clients but at the same time they are eager to develop or extend business relationships with multinationals.⁶ The forced linkage effect highlights a possibly more frictional customer- supplier relationship than one in which multinationals share their proprietary knowledge freely.⁷

The paper by Gorodnichenko et al. (2007) is closest to us as it also uses data from the 2005 BEEPS survey and uses information on supplies to multinationals at the firm level. However, they do not consider the “forced linkage” as a channel through which productivity may be boosted in local suppliers but only ask whether suppliers experience higher productivity growth. As we show below, it is however crucially important to distinguish the effect of supplying to multinationals for firms that experience “pressure from their customers” from those that do not. Furthermore, the identification of a causal effect from supplier status to productivity growth is difficult in the Gorodnichenko et al. (2007) study. They regress productivity growth between 2002 and 2005 on the supplier status of a firm in 2005. Hence, it is difficult to judge whether they estimate the effect of supplying on productivity growth, or whether they pick up the fact that highly productive firms are more likely to become suppliers. Our research design is different in that we use data on productivity growth between 2002 and 2005 and regress this on the supplier status in 2002, exploiting the panel dimension available in the BEEPS data. This set up allows us to be more confident about identification of an effect of the supplier status of the firm on productivity growth. We also combine our approach with an explicit test for exogeneity, using instrumental variables available in the BEEPS data.^{8,9}

⁶ Javorcik (2008) shows using a survey on Czech suppliers of multinationals that 37.5 percent of multinationals mandatory scheduled regular price cuts to their suppliers which might lead to complaints from suppliers. She also shows that more than 35 percent of suppliers report to undertake improvements to satisfy their multinational clients.

⁷ This does not contradict the findings that suppliers might on some occasions receive some effective assistance from their multinational clients as, for example, illustrated by Liker and Choi (2004).

⁸ Another difference is that Gorodnichenko et al. (2007) only use data for 17 countries (due to availability of input-output tables) while we use firm level data for 25 Eastern European and Central Asian countries.

⁹ Our use of panel data implies, however, that our sample size is smaller than if we used the full cross section for 2005. However, in this trade-off between larger sample size and more precise identification of the

To preview our results, we find evidence for a productivity gain of being a supplier only if the supplier status is interacted with a variable indicating that there is pressure from customers. We interpret this as evidence that there is a forced linkage at work and that spillovers do not seem to materialize in the absence of such pressure. This result is robust to various specifications of the empirical model.

In section 2 we develop our empirical strategy, while section 3 discusses the data used and presents summary statistics. The econometric analysis is presented in Section 4. Section 5 provides some concluding comments.

2. Empirical framework

In our empirical analysis we investigate whether there are positive productivity effects from supplying multinationals, and whether these may be due to a “forced linkage”. In order to do so we examine the relationship between productivity growth of a host country firm and its status of whether it is a supplier to a multinational.

More specifically, we estimate the determinants of productivity growth using an augmented Cobb- Douglas production function, which in its most basic form looks as follows¹⁰

$$\begin{aligned} \Delta Y_i = & \alpha^M \Delta x_i^M + \alpha^K \Delta x_i^K + \alpha^L \Delta x_i^L \\ & + \beta_1 s_i^{MNE} + \beta_2 p_i^{CUST} + \beta_3 (p_i^{CUST} \times s_i^{MNE}) + \beta_3 C_i + \mu_j + \nu_c + \sigma_i \end{aligned} \quad (1)$$

estimated effects we opt for the latter. Reassuringly, Gorodnichenko et al. (2007) as well as the companion paper Gorodnichenko et al. (2010) both compare the cross-section results with the smaller set of panel results. They do not find any major differences in results, apart from the fact that coefficients appear less statistically significant in the panel. Hence, if anything, it is likely that we would underestimate any effects.

¹⁰ The production function estimation allows us to estimate the determinants of productivity growth, i.e., the variation in the change of output that is not explained by variations in the growth of inputs. The setup of a one-step production function has been used extensively for analysing the effect of foreign direct investment on productivity; see, for example, Javorcik (2004). An alternative would be a two-step approach, were one retrieves TFP as the error term of a simple production function and in a second step regresses TFP on the spillover variables. We do not follow such an approach mainly for two reasons. Firstly, it is less efficient than the one step estimation. Second, while the two step approach allows the researcher to better deal with potential simultaneity in the production function (see Levinsohn and Petrin, 2003) we cannot implement such an approach due to data limitations.

where ΔY_i , Δx_i^M , Δx_i^K and Δx_i^L , are respectively measures of percentage changes (growth rates) in output, material, capital and labour inputs for firm i over the three year period from the end of 2002 to the end of 2005. We use growth rates of these variables in order to purge any unobserved firm level effects that may impact productivity *levels*. We include a vector of firm level controls C (size dummies and a foreign ownership dummy), and μ_j and ν_c which are industry and country dummy variables that control for any shock that could occur along these aggregates. The remaining error term σ_i is assumed to be white noise.¹¹

The focus of our study is on whether being a supplier to a multinational firm matters for productivity growth. In order to capture this, we include s_i^{MNE} , a dummy variable indicating whether a firm sells to multinationals or not. This variable is constructed using the following survey question:

"What percent of your domestic sales are to: Multinationals located in your country...?"

We set s_i^{MNE} equal to 1 for any firm that sells part of its output to multinational firms in 2002 and zero otherwise. As an alternative variable we also use the actual share of sales to multinationals in a different specification of the empirical model. We use information relating to 2002 as this is prior to the measurement of the dependent variable. This allows us to attenuate potential endogeneity problems between productivity growth and the supplier status.

¹¹ Details of the data source are provided in the next section and variable definitions in the Appendix. All firms are classified according to a broad industry classification: mining and quarrying, construction, manufacturing, transport storage and communication, real estate, renting and business service and other service activities. Compared to studies of backward spillovers where the aggregation of industries is very important, our study does not rely on the aggregation of industries because we use precise information about firms and their business relationship with multinational customers.

The next important variable, p_i^{CUST} , captures whether firms receive pressure from customers to reduce production costs or to create new products based on the following questions in the BEEPS survey:

“How would you rate the importance of [PRESSURE FROM CUSTOMERS] on key decisions about your business with respect to "reducing the production costs of existing products and services"? or “creating new goods and services and new markets by customers”?”

Respondents had to rate the magnitude of such pressure according to a Likert-type scale from 1 (not at all important) to 4 (very important). We use the information available in 2002 in order to generate p_i^{CUST} for each firm. We set p_i^{CUST} equal to one if the respondent answered “very important” to either the question on reducing costs or creating new products. It is zero otherwise.

Following the arguments set out in the introduction, the expected sign for p_i^{CUST} is ambiguous. On the one hand, the underinvestment problem of the supplier becomes more severe when the balance of power is shifted in favor of the customer. In this case, “pressure” is likely to exacerbate the underinvestment problem, reduce the incentives for the supplier and thus lead to less effort, i.e. lower productivity for the supplier.¹² However if a supplier has more than one customer, pressure by one customer to reduce inefficiency may positively affect also output sold to other customers, thus leading to productivity growth.

The main variable of interest is our proxy for “forced linkages”. To generate this, we interact $(p_i^{CUST} \times s_i^{MNE})$. This interacted variable allows us to test whether the effect of supplying a multinational is different depending on whether there is pressure from

¹² Alternatively, firms might report pressure from their customers because of the risk to be let down at short notice or because customers switch their supply sources often. As a result, suppliers are confronted with uncertainty about future demand conditions which is likely to slow down productivity growth.

customers or not.¹³ If there is a forced linkage mechanism, we expect a positive association between firm's productivity growth and pressure from customers in firms supplying multinational customers. Note that this variable is also measured in 2002 in order to alleviate endogeneity concerns.

This set up allows us to distinguish a simple technology transfer between multinational and its customer from the forced linkage effect, where the technology transfer is accompanied by tough demands. The coefficient β_1 , if statistically significant and positive, represents any productivity enhancing effect while β_3 would only be positive and significant if pressure is applied by the multinational.

In order to identify the forced linkage effect more precisely we also introduce, in extensions to equation (1) an additional variable that measures pressure from competitors to reduce production costs p_i^{COMPET} and add also its interaction term $(p_i^{COMPET} \times s_i^{MNE})$.¹⁴ The survey question used to construct p_i^{COMPET} has an identical design to p_i^{CUST} and allows generating a dummy exactly the same way as for p_i^{CUST} : p_i^{COMPET} is equal to 1 if important pressure is reported by a firm in 2002.

One way pressure from competition might be related to higher supplier productivity is provided by Horn et al. (1995). They analyze the design of optimal incentive contracts in an environment with international trade in which a principal cannot monitor the actions undertaken by its supplying agent. In their framework, openness to trade increases competition on product markets through a general equilibrium effect and contributes to higher levels of managerial effort provided by the supplier, and thus improved internal efficiency (i.e. reduced X-inefficiency). If "pressure by competitors to reduce production

¹³ Note that our data only allow us to calculate a variable indicating whether there is pressure from customers, not whether these pressuring customers are multinationals. We only know whether a firm is intensively pressured by customers and at the same time whether it has multinational firms as customers. It is unlikely that the average domestic customer in emerging economies has access to international best practices and the resulting accumulated knowledge that they could impose upon their suppliers.

¹⁴ The survey questions related to all variables are listed in Appendix 1.

costs” is a good proxy for how increased competition impact firms in this framework, then we would expect that high pressure from competitors is related to more managerial effort provided by the supplying agent and thus improved productivity.¹⁵

Including p_i^{COMPET} and $(p_i^{COMPET} \times s_i^{MNE})$ shows whether our interpretation of the forced linkages holds or if pressure from competitors (external to the supplier-multinational relationship) potentially drives the measured forced linkage effect.

In a further extension to the baseline model we also include some other variables that are by their very nature closely related to a more benevolent relationship between customers and their suppliers. These variables are defined in Appendix 1. The first variable uses a question about whether a surveyed firm has acquired a new technology ($TECH_i$). Including this variable together with a variable about whether cooperation with customers resulted in these new technology acquirements ($COOPTECH_i$) permits us to control for a more cooperative learning mechanism.

Note that a potential problem with estimating equation (1) using OLS is that we assume that the suppliers’ status is exogenous. This may be a problematic assumption, in particular because there may be self-selection of more productive firms as suppliers to multinationals (Javorcik and Spatareanu, 2008). However, this problem is likely to be less acute in our case as we define the supplier status in 2002, while productivity growth is calculated between 2002 and 2005. Also, our variable of most interest is the interaction of pressure from customers and the supplier status. There is no clear reason to suspect that among the suppliers of MNEs the most productive ones are also necessarily the most subjected to customers’ pressure. Nevertheless, we check the assumption of exogeneity using an instrumental variables approach. Details are in the results section.

¹⁵ According to Javorcik et al. (2008) competition between suppliers is important for the diffusion of best practices among suppliers in the Mexican soap and detergents industry. They argue that Walmart brought its best standards and practices into Mexico and that those have been quickly adopted by their suppliers’ competitors in this retail industry.

3. Data sources and summary statistics

This paper uses the 2002 and 2005 versions of the EBRD/World Bank Business Environment and Enterprise Performance Surveys (BEEPS) of firms in “transition countries”. This dataset provides ample information on enterprises and their business environment in many emerging countries (see the list of countries in Table 1) in three rounds in 1999, 2002 and 2005. A limited number of firms can be linked in the 2002 and 2005 surveys.¹⁶ In our analysis, we exclusively use the panel component of the BEEPS data. It includes more than 1000 firms that have been surveyed in the 2002 survey as well as in the 2005 survey. This allows us to measure the supplier status, as well as pressure from customers, in the 2002 survey, while productivity growth is calculated from the 2005 data.

[insert Table 1 here]

The survey’s main aim is to allow for a cross country comparison of business activities and, to that end, asks each firm more than 80 questions about their business, the institutional environment and their perceptions about the business environment. The survey sample in each country is stratified by firm size, sector and region. Sector stratification is undertaken to reflect the relative contribution of each sector to the region’s GDP.¹⁷

Great care has been taken to train and advise interviewers in order to minimize potential distortions and irregularities between countries or during each interview. Interviews have been conducted face-to-face and anonymity has been guaranteed to all participants. Still, a typical concern when using survey data is that of individual perception

¹⁶ Unfortunately there is no panel structure linked to the BEEPS 1999 survey.

¹⁷ To be precise, stratification by sector depends on the size of the economy. Very small economies (less than \$15bn GNI) are stratified into manufacturing and non-agricultural sector; small economies (\$15bn to \$100bn GNI) into manufacturing, retail, and rest of non-agricultural sector; medium economies (\$100 to \$500bn GNI) into five manufacturing sectors, retail and rest; large economies (more than \$500bn GNI) into seven manufacturing sectors, retail and rest. This implies that for all economy sizes, the sample should be representative at least of total manufacturing and the non-agricultural economy. As the economy size increases, representativeness of other more narrowly defined sectors increases. Details of the sampling methodology are available at www.enterprisesurveys.org.

bias, since it is common that responses of firms based on surveys are likely to be prejudiced by the general perception of firms (Kaufman and Wei, 1999). Some firms may consistently provide positive or negative answers depending on their general perception of the environment in which they currently operate. In principle, assuming that the bias is uncorrelated among groups of respondents, individual perception bias contributes only to the standard error of estimates obtained from the survey responses. In cross-country surveys, such as the BEEPS, the group within which the bias is correlated is the particular country in which respondents operate. Perception bias at the country level could originate from different cultural norms and degrees of political freedom across countries, which may influence the choice of specific ratings and the willingness of business people to criticise state institutions for example. Fries et al. (2003) check for such perception bias in the BEEPS 2002 by statistically comparing qualitative measures to related objective measures and find no significant perception biases across the countries in the sample. Since the BEEPS 2005 follows a similar methodology, we may be reasonably confident that perception bias will not affect the results of the analysis. However, as a further control, the empirical model in equation (1) includes industry and country level fixed effects.

The BEEPS data provide crucial information for estimating productivity growth and unique information on the share of firms' sales to multinational clients as well as on whether firms feel pressured by their customers to reduce production costs or to create new products.

The survey provides information on changes in input use and output between 2002 and 2005. Specifically, the responding firm has to answer the following question in 2005 for each of the variables in brackets.

"Over the last 36 months how have [sales, fixed assets, material inputs] changed and what is the percent of change for your company, in real terms (i.e. after allowing for inflation)"

A similar question is asked for changes in employment over the same 36 months in each firm and described in Appendix 1. We use answers to these questions as a base for our productivity growth estimation in equation (1). Such data enable us to construct a simple Cobb Douglas production function. We acknowledge that there is a potential simultaneity problem in input choices in the production function estimation, as described, for example, by Levinsohn and Petrin (2003). Unfortunately, we do not have sufficient data to implement the techniques suggested in their paper. However, this potential disadvantage has to be weighed against the advantages of having unique information on pressure from customers reported by their suppliers as well as detailed information on suppliers' sales to multinationals. Such information makes it possible, for the first time, to confront the forced linkages effect with a formal econometric analysis.

Table 2 presents some summary statistics relating to the variables included in the econometric analysis. We describe our whole sample in the top panel. The sample contains 1,012 active firms during the study period. First, note that around 38 percent of our firms reported "very important" pressure from their customers (p_i^{CUST}). Furthermore, 30 percent of firms reported to have developed a new technology ($TECH_i$) while only 2 percent of them responded that customers help them develop their new technology ($COOPTECH_i$). Note also that the average firm in our sample had an increase in sales of about 11 percent between 2002 and 2005.¹⁸ Finally, in the last columns of the upper panel we see that 14 percent of our firms are suppliers of multinationals and the average firm (including non-suppliers) sells 3 percent of their output to multinationals.

We distinguish suppliers from other firms that do not supply multinational customers in the lower panels of the table. We notice some differences in the mean values between both types of firms. First, suppliers of multinationals are more likely, on average, to report pressure from customers than firms that do not supply any multinational. Second,

¹⁸ This growth rate is measured in real terms.

firms serving multinationals are on average more likely to introduce new technologies and especially, they are more likely to cooperate with their customers to obtain these new technologies. Suppliers of multinationals are also more often subject to pressure from competitors than firms that do not sell goods to multinational firms. Concerning economic performance over the period, we note that firms that supply goods or services to multinationals in 2002 seem to have a higher mean output growth over the subsequent three years. The average supplier sells roughly 23 percent of output to multinational customers.

We also distinguish “pressured” suppliers in the table. We have 61 of such firms in our data.¹⁹ These are firms for which the interaction term $(p_i^{CUST} \times s_i^{MNE})$ equals one. We find that these firms are more likely to report pressure from competitors than other suppliers. They are also firms that experience higher output growth in the subsequent periods. However, there is no obvious difference in the share of output sold to multinationals when comparing “pressured” and “non-pressured” suppliers.

[insert Table 2 here]

4 Empirical results

4.1 Baseline model

Table 3 presents the baseline regression results from estimating equation (1) using the supplier dummy s_i^{MNE} . Column (1) shows a simple estimation of a Cobb Douglas production function that is solely augmented by s_i^{MNE} . Note that Δx_i^M , Δ_i^L and Δx_i^K are all positive as expected. A dummy variable for firms that are larger than 250 employees (large size) is also significant and positive. By contrast, dummies for medium sized firms (50 o 249 employees) and foreign-owned firms are not statistically significant. Most importantly from our point of view, the variable s_i^{MNE} which measures whether or not a firm supplies

¹⁹ This relatively small number of firms should be kept in mind when interpreting results.

goods or services to foreign multinational companies located in the host country is not statistically significant.²⁰ It indicates that in our data selling goods to multinationals is not necessarily automatically statistically related to higher gains in productivity.

In column (2) we turn to the estimation of equation (1) that includes s_i^{MNE} , p_i^{CUST} and $(p_i^{CUST} \times s_i^{MNE})$ jointly in our productivity specification. The supplier dummy remains statistically insignificant in this specification. The coefficient on p_i^{CUST} is, however, negative and significant. It suggests that firms that experience high pressure by their customers have lower productivity growth than firms that do not report such pressure. This negative sign is in line with our argument that p_i^{CUST} captures the underinvestment problem resulting from a weakened bargaining strength of the supplier when pressure is exerted by its customers. It reduces the incentives for this supplier and thus is related to less effort and lower productivity.

The coefficient of the interaction term $(p_i^{CUST} \times s_i^{MNE})$, our proxy for the “forced linkage effect” is positive and highly significant. Given that its absolute value is higher than the value of the coefficient of p_i^{PC} , it supports the forced linkage effect. Hence, suppliers of multinationals that are pressured by their customers to reduce production costs or create new products have higher productivity increase relative to all other firms, including other suppliers of multinationals. There is no productivity enhancing effect for suppliers that are not pressured by their customers, thus casting doubt on whether, on average, multinationals transfer technology to their suppliers unconditionally. The point estimate suggests that suppliers that experience pressure from their customers experience productivity growth that is about 11 percent higher than that of other firms.

We might ask whether our proxy for the forced linkage does not capture a mere competition effect through which suppliers of multinationals are forced to adopt their

²⁰ Gorodnichenko et al. (2007) find a similar result when using panel data for 2002 and 2005.

industry's best practices because their domestic competitors apply such practices as well. This could also result in a productivity enhancing effect, but not through the direct supplier-customer relationship (Horn et al. 1995). We consider this hypothesis by enlarging our baseline equation with a variable that considers "pressure from domestic competition to reduce production costs" p_i^{COMPET} and the interaction term $(p_i^{COMPET} \times s_i^{MNE})$.

Results are shown in column (3). First, neither p_i^{COMPET} nor $(p_i^{COMPET} \times s_i^{MNE})$ are statistically significant while $(p_i^{CUST} \times s_i^{MNE})$ is still positive and significant, with a magnitude similar to that found in column (2). This result suggests that the positive coefficient on $(p_i^{CUST} \times s_i^{MNE})$ is not merely driven by a general competition channel in our data.²¹ Rather it gives further support that the benefit of the forced linkage effect and its coercive mechanism runs through the customer- supplier relationship.

In column (4), we enlarge our specification with qualitative variables closely related to a more cooperative mechanism that might channel productivity gains for suppliers because they sell their products to multinational firms. These variables are $TECH_i$, $COOPTECH_i$ and their respective interaction terms with s_i^{MNE} . The introduction of these variables jointly tests whether the beneficial productivity effect induced by the forced linkage is, as hypothesized, the result of tough demands by multinationals or whether it is the result of a more frictionless technology transfer between multinationals and their suppliers. Results show that neither the two variables nor their interaction terms are significant. At the same time, $(p_i^{CUST} \times s_i^{MNE})$ stays positive and significant as before. Thus controlling for collaboration between suppliers and customers in the development of new technologies does not affect the quantitative role of the forced linkage effect in the supplier-customer relationship thus far.

²¹ This finding does not mean that X-inefficiencies are not reduced through competition effects in the spirit of Horn et al. (1995), as such general equilibrium effects might take more time to materialize. Nevertheless, the forced linkage effect is not disrupted when controlling for such a possible channel.

[insert Table 3 here]

In the above estimations, we defined the supplier status of a firm using a binary yes/no variable. However, we also have information on the share of output that is sold to a multinational. We use this information in the results reported in Table 4. We re-estimate equation (1) but now using the share of output and its interaction as independent variables. Results are much in line with the results in Table 3. We find that the share of output sold to multinationals is only positively associated with productivity growth when it is accompanied by pressure from customers. This, hence, provides further support for our hypothesis of a forced linkage effect.

[insert Table 4 here]

4.2 Exogeneity of supplier status

Before we move on to some further robustness checks, we consider the assumption of exogeneity of the supplier status. This assumption would not hold if there were self-selection, whereby the most productive firms might self-select to become suppliers of multinationals (Javorcik and Spatareanu, 2008). One way of alleviating this problem is our definition of the supplier status in the period before productivity growth is measured. Note also that our variable of most interest is the interaction of pressure from customers and the supplier status, not solely the supplier status. There is no reason to suspect that among suppliers of MNEs, those suppliers that exhibit higher pressure from their multinational customers experience it because they have higher productivity growth.²²

Nevertheless, we also test explicitly for exogeneity using an instrumental variables approach. The BEEPS data provides us with a number of potential instruments. We employ two instruments for the supplier status (either dummy variable or the share of

²² In fact, as a referee pointed out to us, the interaction of the supplier status and pressure shows how suppliers are persuaded to improve in light of multinationals' demands – and for this, in some sense, it does not matter whether the supplier status is exogenous or not.

output supplied to multinationals) which are based on two questions in the 2002 survey. The first is a dummy variable that indicates whether a firm ever had to resolve an overdue payment, the second a dummy indicating whether a firm is a member of a business association or chamber of commerce.

We consider the first to be a relevant instrument, as being a supplier necessarily implies the receipt of payment from the customer. However, there may be a difference in the speed and reliability of the payment depending on the nature of the customer. On the one hand, multinationals as opposed to domestic customers, may be more forthcoming with their payments as they are part of a large internationally operating enterprise which is likely to be a reliable debtor. On the other hand, a multinational is likely to be in a strong bargaining position and might optimise its timing of payment flows which could result in payment delays. In any case, the variable is likely to be correlated with the supplier status of a firm. There is, however, no reason to suppose that the receipt of an overdue payment is related to productivity growth of the firm.

The second instrument is also expected to be correlated with the supplier status as the membership of an association or chamber of commerce may make it easier for a local supplier to find customers. Again, however there is no reason to believe that such a membership may be more or less likely for firms with high vs low productivity growth.

Table 5 presents the first stage regression coefficients for the excluded instruments as well as the diagnostic tests. We re-estimate the models presented in columns (2) in Table 3 (supplier dummy) and Table 4 (share of output), respectively, using an IV estimator. Column (1) in Table 5 assumes the supplier dummy to be endogenous, column (2) uses the share of output supplied to multinationals.

Note, firstly, that both instruments are individually significant in the regressions. Given the way these variables are defined, the negative coefficients imply that a firm is more likely to be a supplier (or supply a larger proportion of output to a multinational) if

the firm either had to resolve an overdue payment or is a member of a business organisation / chamber of commerce. The F-tests also suggest that the instruments are jointly relevant, and the F-statistics are above 10, the value generally considered to be high enough to reject the assumption of weak instruments (Staiger and Stock, 1997). The underidentification tests also suggest that we do not suffer from a weak instrument problem. The Hansen J statistics furthermore suggest that our overidentification restrictions are valid, suggesting instrument validity.

Based on these instruments, we then test for the assumption of exogeneity of the two alternative measures of the supplier status in equation (1). We are not able to reject this assumption. Hence, we are confident that our estimations based on the assumption of exogeneity allow us to identify an effect of the supplier status on productivity growth of firms.

[insert Table 5 here]

4.3 Further robustness checks

Table 6 presents the results of two further robustness checks. The first one, reported in columns (1) and (2) uses a slightly re-defined measure of pressure from customers. Recall that in the estimations thus far this is measured as a dummy equal to one if the firm reports that pressure from customers is “very important”. We now redefine this variable as equal to one if the firm answers “very important” or “fairly important” to this question. This, of course, also implies that the interaction terms $(p_i^{CUST} \times s_i^{MNE})$ and $(p_i^{CUST} \times s_i^{MNE})$ are recalculated. The results in columns (1) and (2) are fairly similar to those reported in Tables 3 and 4, with one important exception. The coefficient on the interaction term $(p_i^{CUST} \times s_i^{MNE})$ is no longer statistically significant in column (1). This indicates that the supplier status per se (i.e., measured with a dummy) only has a positive effect on productivity growth if firms are subject to very important pressure from customers.

The analysis thus far includes both domestic and foreign firms. From the perspective of a host country policy maker it may, however, be particularly important to know how domestic firms are impacted upon by their linkages with multinationals. In order to consider this explicitly, we dropped all foreign firms from our sample and re-estimated equation (1) only for the sample of domestic firms. The results, which are very similar to those found in Tables 3 and 4, are reported in columns (3) and (4) of table 6. They support our hypothesis of a forced linkage effect in the customer-supplier relationship between multinationals and domestic firms.

[insert Table 6 here]

5. Conclusions

This paper presents the first empirical evidence of a forced linkage effect in the context of spillovers from FDI using a large sample of more than 1000 firms in 25 emerging economies. We find that productivity gains only materialize for suppliers of multinationals when they are pressured by their customers to reduce production costs or create new products. Suppliers of multinational firms appear to be forced by their multinational customers to adopt some tough demands on product features and business interaction procedures that have a positive productivity effect.

Such an effect of serving multinationals has largely been ignored by the recent literature on backward spillovers. We show that the forced linkage effect holds in various specifications, controlling for other factors that may impact the supplier-customer relationship.

This adds a new policy relevant angle to the spillovers literature. Most of the studies on spillovers through backward linkages at least implicitly, if not explicitly, seem to be based on the assumption of a benevolent multinational that is willing to share knowledge voluntarily and instruct willing suppliers. While our evidence does not indicate that this is

not the case, our results suggest that the customer-supplier relationship may not always be so harmonious. Multinationals' accumulated experience allows them to put pressure on their suppliers to improve production costs or create new products – which also turns out to be to the benefit of the supplier, in terms of increased productivity growth.
