IZA Discussion Paper No. 8538
October 2014

ABSTRACT

Say Pays! Shareholder Voice and Firm Performance*

This paper estimates the effects of Say-on-Pay (SoP); a policy that increases shareholder "voice" by providing shareholders with a regular vote on executive pay. We apply a regression discontinuity design to the votes on shareholder-sponsored SoP proposals. Adopting SoP leads to large increases in market value (4%) and to improvements in long-term performance: profitability and labor productivity increase, while overheads and investment fall. In contrast, we find limited effects on pay levels and structure. This suggests that SoP serves as a regular vote of confidence on the CEO, which leads to higher efficiency and market value.

JEL Classification: G34, M52

Keywords: say-on-pay, corporate governance, executive compensation

* We are grateful to seminar participants and discussants at several seminars and conferences for their helpful comments and suggestions. The paper was written with support from the W.E. Upjohn Institute for Employment, the Spanish Government (ECO2011-24928 and ECO2010-17158), Banc Sabadell, and Bank of Spain's Program of Excellence in Research. Raymond Lim provided excellent research assistance. The usual disclaimer applies.

1. Introduction

How much "voice" should shareholders have in a modern corporation? When shareholders disagree with the course a corporation is taking, and exercising control is not possible or too costly, there are two main mechanisms by which to express their dissent: they can sell their shares (exit), or engage with management and express their opinions, i.e. use the "voice" mechanism (Hirschman, 1970). This paper studies the effect on shareholder value, firm performance and CEO compensation of an important voice channel: Say-on-Pay. Say-on-Pay gives shareholders a voice by allowing them to vote on executive pay, and its relationship to firm performance. Since it is not just a vote on the level of pay per se but on whether pay reflects the value that the CEO adds to the firm it can be seen as an explicit vote of confidence that aggregates the opinions of all shareholders (and not just those that are most visible or active) into a simple, highly visible metric. Indeed, to date, along with the direct election of board members, it is the only mandatory mechanism, that forces firms to regularly allow all shareholders to directly and publicly vote on how the firm is run.[1]

Our goal is to provide a causal estimate of the effects of Say-on-Pay on stock market returns and shareholder value, as well as longer-term effects on accounting performance, firm policies, productivity and CEO compensation. To do this, we use a regression discontinuity design on the vote outcomes of shareholder-sponsored Say-on-Pay proposals at annual meetings between 2006 and 2010. The existing evidence to date is based on the cross-sectional impact of the announcement or implementation of regulatory changes and has found mixed results on the effect of Say-on-Pay: Cai and Walkling (2011) find no effect of Say-on-Pay or average and negative for labor union sponsored proposals,

[1] Some of the other important and related voice mechanisms that have received attention include the role of activist funds in negotiations with management (e.g. Gantchev, 2013), or more general governance proposals (e.g. Gillan and Starks, 2000, 2007; Cuñat, Gine and Guadalupe, 2012).

Larcker, Ormazabal and Taylor (2011) do not find a consistent pattern either, but Ferri and Maber (2010) find generally a positive effect of Say-on-Pay. We complement and contribute to the existing literature along two dimensions. First, we provide an identification strategy that is particularly well suited to isolate a causal effect of Say-on-Pay on stock returns. Second, we study the changes in performance, firm policies and CEO compensation resulting from the Say-on-Pay vote, which allows us to provide evidence on the channels through which Say-on-Pay operates.

Proponents of Say-on-Pay argue that it strengthens shareholder oversight and can limit executive compensation excesses. Its critics counter that it undermines the power of the board and can be very costly to the firm, a view seemingly borne out by the way in which it is systematically opposed by management. Indeed when we looked at the proxy materials mailed to shareholders of the firms in our sample, in over 99 percent of cases management recommended to 'vote against' the shareholder-sponsored Say-on-Pay proposal.[2] In 2010, the Dodd-Frank Wall Street Reform and Consumer Protection Act made Say-on-Pay compulsory at all U.S. firms with effect from 2011, a measure that continues to be a source of contention.

However, the debate on the merits of Say-on-Pay has been hampered by a lack of causal evidence on its consequences; in particular on the performance effects of Say-on-Pay beyond the short-term market reaction. The adoption of Say-on-Pay is correlated with multiple firm attributes that also affect performance and hence is highly endogenous. Moreover, investors incorporate expectations as they receive information on the value of adopting a Say-on-Pay proposal. It is therefore difficult to capture its effect on market prices in the absence of individual

[2] This highlights the strong resistance to these proposals by management. This opposition, which is common to most shareholder-sponsored proposals, contributes to the high costs of a garnering enough votes to pass proposals (as highlighted by Gantchev, 2013), even when passing them is associated with positive market reactions.

unexpected events where new information is released.

To address these concerns, we use votes on Say-on-Pay proposals at annual meetings as a quasi-experimental setting. Our sample includes 250 cases of proposals to adopt the Say-on-Pay policy filed with the SEC by shareholders of S&P 1500 firms between 2006 and 2010.[3] We use a regression discontinuity design that compares the stock market reaction and other outcomes of Say-on-Pay proposals that pass by a small margin to those that fail by a small margin. The intuition behind this strategy is that the characteristics of firms where a Say-on-Pay proposal passes with 50.1% of the vote will be similar to those where it gets 49.9% and fails to pass. However, this small difference will have a major impact on the probability of the proposals being implemented. In other words, for a 'close call', passing is akin to an independent random event that is correlated with the implementation of the proposal but is 'locally' exogenous (uncorrelated with other firms' characteristics). We show that for votes around the threshold, passing is uncorrelated with the observed firm and meeting characteristics. Moreover, when studying the stock market reaction, it is precisely in such close-call situations that the vote contains substantial information — switching from an unpredictable outcome to either pass or fail— that is not already fully incorporated in the stock price. Thus the regression discontinuity design delivers a causal estimate of the expected value of adopting Say-on-Pay.[4]

We find that Say-on-Pay significantly increases shareholder value. On the day of the vote, a Say-on-Pay proposal that passes yields an abnormal return of 2.4%

[3] Note that we study the votes to adopt the policy. If the policy is adopted, shareholders vote on the relationship between CEO pay and performance in subsequent meetings.

[4] Cuñat, Gine and Guadalupe (2012) also use a regression discontinuity design to study a different set of governance issues. Here, we focus on Say-on-Pay, an inherently interesting policy given its controversial nature and the quick expansion of firm policies and regulation over a brief period of time. Over our sample period there are sufficient proposals to study Say-on-Pay using an RDD, such that we do not need to pool different types of proposal for the analysis. Further, since the sample of firms and the time period under study are also different from Cuñat, Gine and Guadalupe (2012), the two papers are complementary and jointly paint a richer picture of the effects of different governance structures.

relative to one that fails. Since the outcome of the vote is not binding, the market reaction should only account for the increase in the probability that the proposal will be implemented after a positive shareholder vote. We collected information on whether each proposal in our sample was implemented, and find a 52.5% higher probability of implementation for proposals that narrowly pass the threshold, implying that Say-on-Pay will deliver an increase in shareholder value of about 4% (3.4% to 4.6%, depending on the estimates). This is of the same order of magnitude as removing two anti-takeover provisions (as estimated in Cuñat, Gine and Guadalupe, 2012). We also show that this effect is driven by Say-on-Pay itself and not by other proposals that are voted on the same day.

Where do these large market gains come from? In principle, there are two distinct channels through which a Say-on-Pay policy can improve firm performance. First, by giving shareholders a mechanism through which to express their opinions, it increases board monitoring and pressure on the CEO to increase performance. In particular, given that a negative Say-on-Pay vote can have significant consequences on the CEO's career. Second, Say-on-Pay can potentially affect the level and structure of executive pay, such that there is a greater alignment with performance.

Our results confirm that Say-on-Pay has a positive impact on firms' accounting and operational performance in the years following the vote (that is, beyond the short-term market reaction). Firms that implement Say-on-Pay have higher growth in earnings per share, return on assets, return on equity and Tobin's Q one year after the vote. They also see a higher increase in productivity (sales per worker) one year and two years after the vote, and they reduce their overheads (SG&A) and capital expenditure; suggesting increased efficiency along different dimensions. In short, there is evidence of efficiency and profitability gains achieved through the implementation of Say-on-Pay proposals.

The effects on executive compensation are smaller. We find no systematic change to the level or structure of CEO compensation, or to the probability that the CEO leaves the firm after a positive Say-on-Pay vote. There is a slight reduction (four percent) in the rate of salary increases. While there are significant changes in the composition of pay, these are not consistent across measures or over time. No systematic pattern in changes to compensation is apparent, although the lack of an average effect on the level or structure of compensation may mask the fact that different firms adjust compensation along different (and maybe opposing) dimensions. In short, we find no evidence that Say-on-Pay leads to large, across-the-board reductions in executive compensation.

In sum, our findings suggest that Say-on-Pay serves to monitor and incentivize CEOs to deliver better firm performance by providing a clear mechanism for shareholders to voice their opinions, as confirmed by major improvements in shareholder value and firm performance among the firms in our sample**.**

Given the evidence that Say-on-Pay significantly benefits shareholders, why don't all firms embrace it? Within our sample firms' management is systematically opposed to Say-on-Pay, but our results suggest that where the proposal narrowly failed shareholders would have benefited from it passing, yet it did not get sufficient support. This suggests a fundamental misalignment of objectives between management, boards and shareholders. Shareholder voting is only partially correcting this misalignment: Some shareholders may have other stakes in the firm that make them vote in ways that do not maximize shareholder value.[5] Moreover, strategic voting can lead to contested votes even when a large majority of shareholders' has a similar opinion.[6] These deviations from shareholder value maximization imply that very relevant proposals with well-

[5] For example, banks and insurance companies tend to side with management by voting against the proposals, while mutual funds, unions, advisors, and pension funds tend to support the proposals (Brickley, Lease, and Smith (1988), Agrawal, (2008)

[6] The strategic voting theory was introduced by Austen-Smith and Banks (1996) and Feddersen and Pesendorfer (1998). Maug and Rydqvist, (2009) show empirical evidence of strategic voting in corporate voting.

defined value implications can still experience contested votes. They also underscore minority shareholders' difficulty to bring about change.

Another possibility is that the positive effects are confined to firms in our sample which proposed to adopt Say-on-Pay – and hence the returns to implementing the proposal were largest (regression discontinuity yields, by design, a local estimate). The firms in our sample, are larger than the rest of S&P 1500 firms, but the difference in operating ratios or other variables is significantly reduced or disappears once size is controlled for. This is consistent with the findings in Cai and Walkling (2011) and must be kept in mind when extrapolating our results to a broader set of firms. In contrast, for the firms in our sample, there are no big differences between firms around and outside the discontinuity suggesting that it may be possible to extrapolate the results to the set of firms outside the discontinuity. (See Appendix Table A1)

Our findings contribute to the discussion around the appropriate role of government regulation and shareholder activism in shaping corporate governance structures. Say-on-Pay is compulsory in many countries (e.g. U.S., Netherlands, Norway, Switzerland, U.K.). However, the controversy around Say-on-Pay continues.[7] Since this paper provides evidence that Say-on-Pay can have substantial positive effects on firm value and performance, it should help to guide the debate.

2. Background

2.1. Say-on-Pay Policies

Say-on-Pay policies are the result of a general trend towards requiring greater executive accountability, transparency, and shareholder rights. They have

[7] While the Dodd-Frank Financial Regulation Act made Say-on-Pay compulsory as of 2011, the Jumpstart Our Business Startups (JOBS) Act of 2012 eliminated the requirement for firms with gross annual revenues of less than $1 billion.

emerged following an increase in the number of shareholder proposals on compensation-related matters submitted to a vote at annual meetings (see Ertimur, Ferri and Muslu, 2011 for an analysis of shareholder activism and pay).

Our data consists of 250 shareholder proposals filed with the SEC between 2006 and 2010, to give shareholders an advisory vote on executive pay (see Table 1). Firms that adopt Say-on-Pay commit to giving shareholders a regular vote on whether executive pay is commensurate with firm performance. Companies such as Motorola, Target, Raytheon and Pfizer were all 'targets' of Say-on-Pay proposals in that period.[8] This increasing focus on Say-on-Pay in the U.S. culminated with its incorporation in the Dodd-Frank Act (July 2010) that regulates the governance and disclosure practices of public companies. Among other provisions, it gave shareholders the right to a regular advisory vote on current and future executive compensation. As of 2011 this has been mandatory for all U.S. listed firms.[9]

Proponents of the bill claim that Say-on-Pay strengthens the relationship between the board, executives and shareholders, ensuring that board members fulfill their fiduciary duty. Critics insist that Say-on-Pay does not effectively monitor compensation, and is an intrusive measure that undermines the board's authority.

On average, shareholders voted 43% in favor of adopting Say-on-Pay proposals (Table 1). This is larger than the average vote on corporate governance shareholder proposals (36%) and relative to all other compensation proposals

[8] A noteworthy case was the Verizon Say-on-Pay proposal in 2007, which was approved by a narrow majority of 50.18%. The board decided to implement it starting in 2009. Shareholders gave the following rationale for proposing to adopt Say-on-Pay at Verizon: "We believe that the current rules governing senior executive compensation do not give shareholders sufficient influence over pay practices — nor do they give the Board adequate feedback from the owners of the company". This suggests increased voice, in the form of increased "feedback" and "influence" was an important goal of the proposal. The proposal also stated that Say-on-Pay would "...encourage shareholders to scrutinize the new, more extensive disclosures required by the SEC," suggesting that the incentive for shareholders to monitor increases when they have better tools to take action (a recurrent argument in Hirschman, 1970).

[9] The Dodd-Frank Act required an additional vote regarding the frequency of the compensation approval vote: to occur every 1, 2, or 3 years.

(23%).

2.2. Expected effects of Say-on-Pay

Given that Say-on-Pay votes are non-binding, it could be argued that it should have no effect on executive or director behavior, and hence firm outcomes. However, given the potential costs associated with it (e.g. legal costs, cost of managing the relationship with investors), the net effect of putting Say-on-Pay in place may well be negative even if it has no effect on behavior. It may also be detrimental in other respects. For example, since the board of directors is more informed about the company than the average shareholder, it should be better placed to make decisions. Likewise, directors and CEOs may have access to information that is best withheld from the market; restricting their freedom to decide may be value-destroying for shareholders.

There are a number of channels through which Say-on-Pay may positively affect firm performance. A popular view is that Say-on-Pay curbs excessive executive pay, although the potential gains from the point of view of shareholder value are modest relative to total firm value. A slightly different mechanism operates via a better alignment of pay with performance: any improved incentives resulting from Say-on-Pay should make CEOs more effective at generating higher profits. Finally, Say-on-Pay allows shareholders to express dissent. Where adopted, it becomes an established part of the votes that shareholders cast at annual meetings that is likely to be as prominent as the election of new directors. Since it is the only regular vote on the link between pay and performance, it is akin to a referendum or vote of confidence in the CEO – empowering shareholders by providing a mechanism through which they can punish a CEO for poor performance. Even though the outcome of the vote is purely 'advisory' (rather than binding), it aggregates shareholder opinion into a simple, visible metric and may serve to coordinate further action to remove management or board members. It gives shareholders a "voice" (Hirschman, 1970) with which they may discipline managers, making their monitoring (and the incentive to monitor) more effective.

2.3. Related Literature

The existing empirical evidence on Say-on-Pay mainly exploits announced or effective legal changes in the U.S.--which are arguably exogenous to the firm--combined with different ex-ante classifications of which firms should be more or less affected by the legislation. Cai and Walkling (2011), using an event study methodology, find that the Say-on-Pay bill passed in the House of Representatives in April 2010 created value for firms with inefficient executive compensation and with weak governance. Larcker, Ormazabal and Taylor (2011) examine a broader set of legislative events on several aspects of pay (including Say-on-Pay) and found no consistent pattern in market reactions to such events. Ferri and Maber (2013) examine the implementation of Say-on-Pay regulation in 2002 in the United Kingdom and find a positive market reaction to the regulation in firms with weak penalties for poor performance. They also find some evidence that legislation increased the sensitivity of CEO pay to poor accounting performance (but not to stock performance), that is, it curbed “pay for failure” problems. To date, however, there is no evidence on the impact of Say-on-Pay on the detailed components of pay in the U.S. or on long-term firm performance in any of these countries.

Relative to the regulatory event-study based evidence, our approach has the advantage of allocating firms to treatment and control groups using small differences in votes, that randomly assign them around the majority threshold. This generates treatment and control groups that are comparable in observable and unobservable characteristics. Conversely, regulatory event studies require the researcher to choose these groups ex-ante and assume common trends and the absence of spillovers. A second advantage is that we study the pre-mandatory period (2006-2010) and focus explicitly on Say-on-Pay votes at the *firm level*; generating events that are idiosyncratic and at different points in time. Hence, our results are unlikely to be confounded by various items, news or information being released to the market on the same date as the legislative event. Legislative events also generate aggregate changes in the overall market for CEOs and spillovers on *non-treated* firms. This is particularly relevant in this setting, in which legislative changes are often bundled, or may contain information about future policy changes. As discussed below, our estimation strategy (the regression discontinuity design) deals with this problem and actually estimates a causal effect.

Cai and Walkling (2011), also analyze firm level proposals of shareholder Say-on-Pay between 2006 and 2008. In contrast to what we find in this paper, they find generally insignificant effects, and actually negative effects for proposals by labor unions. These, are associated with negative abnormal returns when announced, and positive when defeated. A relevant methodological difference between this paper and Cai and Walkling (2011) is that they compare all the proposal announcements and outcomes (pass/fail), which is likely to be correlated with omitted firm characteristics (such as the strength of unions in the firm). Instead, we focus on proposals around the voting majority threshold to use a form of exogenous variation.

3. Data and identification strategy

3.1. Data description

We obtained data on Say-on-Pay proposals from Riskmetrics. The dataset includes information on all the proposals voted on in the S&P1500 universe and an additional 500 widely held firms. Our sample consists of 250 shareholder-sponsored proposals voted on at annual meetings from 2006 until the 21st of July of 2010 to implement Say-on-Pay provisions.[10] Riskmetrics provides information on the company name, the date of the annual meeting and the percentage of votes in favor of the proposal[11].

Panel A of Table 1 shows the distribution of proposals by year and some vote statistics. The number of voted proposals increased throughout the period as well as the proportion of votes in favor. As a result the percentage of proposals passed increased from 15% in 2007 to 25% in 2010. Our identification strategy relies on proposals with a close-call outcome. More than half of the proposals in our sample fall within ten percentage points of the majority threshold.

We used additional information from a number of sources: security prices from CRSP were used to calculate daily abnormal returns with a standard unrestricted OLS market model and also with the three Fama-French factors plus a momentum factor as in Carhart (1997).[12] Financial information came from Compustat and executive compensation from Execucomp. Table 2 presents descriptive statistics of our sample and defines all the variables used in the paper.

3.2. Identification strategy

We are interested in the impact of passing a Say-on-Pay proposal on an outcome variable for firm f at time t, y_{ft} (this can be the stock market reaction or subsequent performance and pay policies). We define v_{ft} as the votes in favor of a

[10] The end date of the sample is chosen to match the date in which the final bill that makes Say-on-Pay compulsory was signed. The last observation in the sample corresponds to the 11th of June of 2010. A total of 258 proposals were filed with the SEC in the sample period. To avoid the risk that our results are driven by a few proposals, throughout the paper, we drop observations with extreme abnormal returns (firms above the top and below the bottom 1%) on the day of the vote. We also drop those firms with missing abnormal returns on the day of the vote. This leaves us with a sample of 250 observations. The overall results in the paper are qualitatively similar if we use all observations.

[11] Two observations were reported to have exactly 50% of the votes in favor, so we checked whether they were considered to have passed and they did not. We therefore code them as "fail" with 49.9% of the vote.

[12] The estimation period is 200 days, ending two months prior to the event date.

Say-on-Pay proposal, v^* as the majority threshold for a proposal to pass and an indicator for pass as $D_{ft} = 1(v_{ft} \geq v^*)$, and write:

$$y_{ft} = K + D_{ft}\theta + u_{ft} \quad (1)$$

The effect of interest is captured by the coefficient θ, while the error term u_{ft} represents all other determinants of the outcome ($E[u_{ft}] = 0$). However, this regression is unlikely to give a consistent estimate $\hat{\theta}$, for instance because passing a proposal is correlated with omitted variables that are themselves correlated with y_{ft}, or in the presence of reverse causality, such that $E(D_{ft}, u_{ft}) \neq 0$.

To obtain a causal estimate of the effect of Say-on-Pay proposals we use a regression discontinuity estimate, which exploits the fact that in an arbitrarily small interval around the discontinuity (the threshold v^*) whether the proposal passed or failed is akin to a random outcome. Lee (2008) shows that as long as there is a (possibly small) random component to the vote, the assignment to "treatment" (pass and $D_{ft} = 1$) and "control" groups (fails and $D_{ft} = 0$) is random around the threshold. A simple nonparametric way to estimate $\hat{\theta}$ is therefore to measure the difference in average y_{ft} between Say-on-Pay proposals that either pass or do not by a narrow margin of votes. This is an unbiased estimate of θ that can be interpreted as causal. However, a more efficient way to estimate the effect consists of fitting a flexible function that captures the continuous relationship between y_{ft} and v, allowing for a discontinuous jump at the discontinuity v^*. Following Lee and Lemieux (2010), we approximate the underlying relationship between y_{ft} and v_{ft}, with two different polynomials for observations on the right-hand side of the threshold $P_r(v_{ft}, \gamma^r)$ and on the left-hand side of the threshold $P_l(v_{ft}, \gamma^l)$, and we also include year dummies α_τ :

$$y_{ft} = D_{ft}\theta + P_r(v_{ft}, \gamma^r) \; + P_l(v_{ft}, \gamma^l) \; + \alpha_\tau + u_{ft} \quad (2)$$

The polynomials $P_r(v_{ft},\gamma^r)$ and $P_l(v_{ft},\gamma^l)$ capture any continuous relationship between y_{ft} and v_{ft}, in particular, the effect of any confounding factors that are correlated both with the vote and firm characteristics in a continuous way.[13] At the same time, θ captures the discrete changes in y_{ft} at the majority threshold, and is a consistent estimate of the causal effect of the passing of a proposal on y_{ft}.[14] This procedure is a more efficient way to estimate the effect than a simple comparison of means around the threshold as all the observations participate in the estimation. The estimate of θ captures the weighted average effect across all firms, where more weight is given to those firms in which a close election was expected. In what follows, we report a polynomial of order three to each side of the discontinuity. We also checked that overall the results are robust to using polynomials of order four and five, as well as to using the non-parametric approach proposed by Calonico, Cattaneo and Titiunik (2014).[15]

Note that the combination of a regression discontinuity design with an event study setting has some additional desirable properties that are absent from traditional event studies. First, to the extent that the market can predict the vote, votes that win or lose by large margins will already be incorporated into prices prior to the vote and hence we should expect no significant price reaction far from the discontinuity. The closer the actual vote is to the discontinuity, the higher the ex-ante uncertainty that is resolved by the outcome of the vote (whether the proposal effectively passes or fails). Hence we expect the largest market response around the discontinuity. In fact, how fast the abnormal return becomes zero as a

[13] We are considering other events at the annual meeting as part of the regression noise. This is correct as long as other unexpected events are not correlated with a close-call pass or fail. We confirmed that a close-call pass on Say-on-Pay does not predict whether a close-call vote on other proposals in the same meeting will pass or fail. An alternative approach is to estimate a discontinuity model for all the proposals in a meeting simultaneously, as in Cuñat, Giné, Guadalupe (2012). The results for this method yield very similar results as can be seen in Table A3. For simplicity and parsimony we use the simpler specification of equation (2) throughout this paper.

[14] Say-on-Pay proposals are not binding. However, they have well-defined majority rules, which we use to calculate our vote margins. Given this, we are in a "fuzzy discontinuity design" setting and are estimating an Intent to Treat effect. To obtain the Treatment on the Treated, we could instrument whether the proposal is implemented with the vote outcome. However, as we show in Section 4.2, while discontinuous at the threshold, the vote does not predict implementation with strong enough significance to have a good first stage. Hence the paper shows Intent to Treat effects (ITT), although we provide an estimate of the treatment on the treated for the market value response by rescaling the ITT effect over the change in the probability of implementation at the discontinuity.

[15] Results available upon request.

function of the distance to the threshold is an indication of the precision with which the market was able to predict the vote. Second, the prior expectations of the market about the implementation of the proposal are identical on both sides of the discontinuity, so the combination of an event study with a regression discontinuity design naturally takes care of any anticipated events prior to the vote. Appendix figure A4 shows the predicted change in abnormal returns as a function of the vote share: it is highest (lowest) just to the right (left) of the threshold, and is closer to zero the further away the vote share is from the threshold.[16]

3.3 Sample characteristics, external validity and pre-existing differences

In this section we investigate two selection issues that are important to understand the external and internal validity of our results. The first is to assess whether the firms identifying our effect are representative of a broader population of firms. The second relates to the selection of firms within our sample into treated and non-treated firms. To the extent that the exact vote outcome around the threshold is random, our identification strategy implies there is no selection into treatment around the discontinuity, that is, firms that pass a Say-on-Pay provision by few votes should ex-ante be comparable to firms that reject a Say-on-Pay provision by a small margin. We run a number of tests to evaluate the validity of this assumption.

First, since the Riskmetrics sample only includes the subset of firms targeted by votes on Say-on-Pay, we compare those to the population they are sampled from (S&P 1500 firms). Appendix Table A1 presents detailed summary statistics of firm characteristics for firms in our sample as well as for the universe of

[16] Cuñat, Giné, and Guadalupe (2012) give a more detailed account of these properties and show that the regression discontinuity estimate captures the expected value of the proposal (given implementation probabilities) after a positive vote. More generally, they show the conditions under which the value of implementing a proposal can be recovered in an event-study setting from the regression discontinuity estimate.

S&P1500 firms, both in 2005. A systematic difference between them appears to be firm size. Larger firms are significantly more likely to hold a Say-on-Pay vote: they have higher total market value, more employees, higher total CEO pay and less dispersed ownership[17] – all characteristics of large firms. As is common among larger firms, they also have higher leverage and, accordingly, higher return on equity. However, once one looks at other profitability ratios that control for size and leverage the differences become smaller or disappear (as is also shown in Cai and Walkling, 2011). Similarly, total annual CEO pay is larger in our sample relative to the whole of Execucomp (average of $11m and $5m respectively). However, if we compute the residual of total CEO pay after controlling for firm size (assets) and market returns the difference in pay drops under $400k and it is not statistically significant.[18] These sample characteristics, do not affect which firms are treated within our sample, and, hence, do not bias our estimate of the treatment effect. However, the fact that the sample tends to include the larger and more prominent firms of the S&P1500 should be taken into account when generalizing the results to a broader population of firms.[19]

Second, in Appendix Table A1 we also compare the characteristics of firms around the discontinuity (within ten percentage points of the majority threshold) to the whole sample. We find that the subsample around the discontinuity is very similar to the whole population. All the variable means are statistically the same except for a small significant difference in top-5 ownership concentration (22%

[17] In the bottom panel of Table A1 one can see the typical structure of votes in our sample. Institutional investors have on average 72% of the votes, although these are quite dispersed among them. There are on average two shareholders with holdings above 5% and the top five investors accumulate on average 21% of the votes. In none of our observations do the top 5 shareholders accumulate enough votes to constitute a majority of votes. On average, a substantial number of votes are held by dispersed shareholders, which reduces the ex-ante predictability of the vote. Note that we restrict the comparison to 2005 to avoid that the year stratification or the effects of Say-on-Pay could drive the results.

[18] We compute abnormal pay as a residual of a regression of total pay on second order polynomials on assets and market returns that are allowed to vary by industry (variable labeled "abnormal pay" in Table A1).

[19] Iliev and Vitanova (2014) find results consistent with ours among smaller firms. They use an event study methodology paired with cross sectional regulatory differences to examine the effect of Say-on-Pay on firms of sizes with share float between $40 million and $110 million. This additional evidence on quite small companies complements ours and contributes to establishing the external validity of the effects found here.

vs. 24%). Overall, there is no evidence of selection into the discontinuity.[20]

Third, in Appendix Table A2 we investigate whether there are any systematic pre-existing differences between firms that pass Say-on-Pay and those that do not. We find some differences when we compare all firms that pass Say-on-Pay to all those that do not, indicating that the decision to adopt Say-on-Pay is endogenous to firm characteristics. However, these differences mostly disappear around the discontinuity, i.e. when we estimate specification (2) using firm characteristics prior to the vote as the dependent variable (a detailed discussion of the table can be found in the Appendix). This absence of observable differences around the discontinuity lends support to our identification strategy.

Finally, we analyze the distribution of shareholder votes. Figure 1 shows the distribution of votes within the sample. First, the average and median vote is slightly below the majority threshold, but 64% of the observations fall within 10 percentage points of the majority threshold. This implies that our regression discontinuity coefficient is estimated from a large and significant share of the actual votes and hence can be thought of as representative of the effect of Say-on-Pay on the average firm in our sample. Second, Figures 1 and 2 show that the distribution of votes is continuous at the 50% threshold, suggesting that there is no strategic voting or withdrawal of proposals for close-call votes. [21]

Overall, this section shows that the assumptions behind our identification strategy — continuity of votes at the majority threshold and lack of preexisting differences in the neighborhood of pass — do hold and allow us to estimate a

[20] If one interprets shareholder votes as a random variable with heterogeneous distributions, an interpretation of the RDD estimator is that it is a weighted coefficient of all firms, with weights reflecting the probability of each firm-proposal to make it to the discontinuity (see Lee and Lemieux 2008). The estimator by Calonico, Cattaneo and Titiunik (2014) is developed under this assumption.

[21] The formal continuity test in Figure 2 (see McCrary 2008) rejects the discontinuity of the distribution at the majority threshold. Cuñat, Giné and Guadalupe (2012) show a similar lack of strategic behavior around the discontinuity for all shareholder-sponsored proposals, while Listokin (2008) documents that strategic withdrawal of proposals is a real issue for management-sponsored proposals (which implies this analysis should not be done on management proposals). Note that, as long as agents are not able to precisely predict the vote, any form of strategic voting would not affect the results at the discontinuity. This applies, among others to ISS recommendations and block holders. The results in Figures 3 and 4 confirm that the market is not able to predict the vote outcomes with such precision.

clean causal effect. It also shows that the main distinguishing difference between firms in our sample and the sampling universe is firm size, which should be taken into account when generalizing the results to a broader population of firms.

4. Results

4.1. The effect of Say-on-Pay on abnormal returns

To evaluate the impact of Say-on-Pay provisions on shareholder value we first examine the market reaction to passing a Say-on-Pay proposal. Table 3 reports estimates of the difference in abnormal returns between Say-on-Pay proposals that pass and those that do not. Columns 1 to 5 present non-parametric estimates. To isolate the causal effect of Say-on-Pay on value, under our identification strategy, we estimate θ as the difference in abnormal returns between proposals that pass and those that do not pass for increasingly small intervals around the majority threshold. Column 1 estimates are based on the whole sample. As expected, we find that there is no difference, on average, between proposals that pass and those that fail (a small point estimate of -0.00210 that is not statistically different from zero) reflecting that for proposals that pass or fail by a large margin, the market has already incorporated the expected vote outcome in prices. Columns 2 and 3 restrict the sample to within ten percentage points and five percentage points of the threshold, respectively. As we narrow the margin of votes around the pass threshold, we begin to see a small increase in the estimates, though the standard errors are still large. For votes within two and half percentage points of the threshold (column 4), we observe an estimate of 1.39% abnormal return that is significant at the 5% confidence level. Finally, if we narrow the window to within one and half percentage points, we observe that the estimate still follows an increasing pattern, reaching a statistically significant abnormal return of 1.88%.

Column 6 shows the regression for equation (2) for the entire sample, when we allow for a discontinuous jump at the majority threshold, but we control for two polynomials of order three in the vote share on each side of it. The results are consistent with the non-parametric ones: the abnormal return of firms that pass a Say-on-Pay proposal is 2.4% higher than for firms that do not pass such proposals. The point estimate in column 6 is larger and more precisely estimated than that in column 5, but the two estimates are not statistically different.

Panel B of Table 3 shows the same set of regressions using as an alternative benchmark the four factor model. We find a similar pattern of increasing estimates as we narrow the interval around the threshold. When fitting a polynomial on each side of the threshold we obtain an estimate of the differential abnormal return of 1.76%, which is statistically significant at the 5% level.

Another way of visualizing these results is to plot the abnormal returns on the day of the meeting. Figure 3 shows the impact of passing Say-on-Pay proposals on abnormal returns on the day of the vote. The daily abnormal returns were calculated from CRSP using the Market model for Figure 3 (results are similar with the four factor model). The graph plots the smoothed average daily abnormal return for the day of the meeting (t = 0) when the information of the vote is revealed. The X-axis reflects the margin of victory (the vote share minus the threshold for that vote). On the day of the vote, Say-on-Pay proposals that pass by a small margin have positive abnormal returns. Comparing those to proposals that fail by a small margin gives us the effect of passing Say-on-Pay on abnormal returns. For votes further away from the threshold the abnormal return is indistinguishable from zero. One could be concerned that outliers could drive the shape of the figure, so in Figure 4 we replicate the exercise using medians: each point in the graph computes median (instead of mean) abnormal returns of the 20 nearest vote outcomes and shows very similar results.[22]

[22] Each point in the y axis represents the median abnormal return (on the day of the vote) of the ten nearest votes along

In our data, proposals that pass with a very small margin of victory (up to 3%) have a positive abnormal return, and this decreases sharply with the distance to the threshold, suggesting that the market is able to predict votes that pass by large margins. Similarly, proposals that fail by a small margin have a negative abnormal return, and the return is decreasing in the vote share to the left of the threshold.

Even if a substantial part of the information about the vote is released on the day of the meeting, we explore any further gains (or potential reversals) beyond the day of the vote.[23] Table 4 reports the regression for equation (2) where the outcome variable y_{ft} denotes abnormal returns computed in different event windows around the day of the vote. We use the entire sample of data and a polynomial of order three in the vote share on each side of the threshold. First, in column 1 the dependent variable is abnormal returns the day before the vote. The small and statistically insignificant coefficient indicates that the effect of Say-on-Pay is not foreseen by the market the day before the vote for any of the benchmarks in Panels A and B. Column 2 shows the effect on the day of the vote (identical to column 6 of Table 3). Next, in Column 3 onwards we find that passing a Say-on-Pay proposal delivers abnormal returns beyond the day of the vote. Column 3 shows the impact on a two-day window that includes the day of the vote and the following day. The coefficients are 2.4% for the market model and 2.1% for the four factor model, which are close to the ones on the day of the vote and statistically significant. Column 4 displays a similar estimate for the two-week window: 2.5% for the market model and 2.4% for the four factor model. Finally, Column 5 shows growing estimates of 5.2% and 7.2%, for cumulative returns up to six weeks; indicating that there is no reversal six weeks after the

each side of the x axis. The discrete jumps in the graph correspond to changes in the median observation as the window changes. The advantage of this approach is that the results are not sensitive to the presence of outliers or driven by a few observations.

[23] Say-on-Pay proposals are closely followed by the media. Moreover, a variety of channels such as newswires and real-time broadcasts disclose the vote outcome on the day of the annual meeting.

vote. Standard errors are much larger (and estimates not significant) in longer windows, since there are many other events driving stock prices and creating noise, although the fact that there is no reversal in the estimated coefficients suggests that the Say-on-Pay effect is persistent.

Overall, we find that the large positive market reaction to passing a Say-on-Pay proposal is sustained and even increases following the vote. We perform two robustness checks in Appendix table A3 related to the presence of other proposals and the dynamics of abnormal returns.[24] First, we directly control for other governance proposals that are voted on in the same annual meeting by adding them linearly to equation (2) and including another polynomial in the vote share for those proposals. The results on Say-on-Pay are similar (See columns 1 and 3 of Table A3) after including these controls. Second, we use a dynamic RD estimator that estimates the effect of the vote on all periods simultaneously and also controls for other proposals (and their vote share polynomial) (see Columns 2 and 4 in Table A3). The results are again very similar. This confirms that the vote outcome of other proposals is not systematically related to the outcome of the Say-on-Pay vote around the discontinuity, such that we can use throughout the simpler specification of Equation (2). In the following sections we go beyond the stock market reaction and explore the different channels that may be driving this market reaction.

4.2. Implementation

This section documents how much the implementation probability of a Say-on-Pay proposal changes at the majority threshold, with three main objectives in mind. Firstly, given that the vote outcome on shareholder proposals is typically

[24] The methodology in Table A3 follows Cuñat, Giné and Guadalupe (2012) and is described in the Appendix.

non-binding it is important to establish whether passing a proposal has an impact on implementation. Secondly, our identification strategy relies on a discontinuity (a discrete change) in the implementation probability of a Say-on-Pay proposal at the majority threshold, so it is important to explicitly test for this assumption. Finally, while we have established the market reaction to passing a proposal, this market reaction takes into account the fact that proposals will be implemented with a certain probability. In order to estimate the actual value of implementing a Say-on-Pay proposal we need to re-scale the market reaction, dividing by the discrete change in the probability of implementation around the vote threshold between passing and not passing.

We collected complete implementation data from SEC filings for all voted proposals in our sample. In particular we recorded whether the proposal was implemented before the following annual meeting. The graph in Figure 3 illustrates the empirical probability of implementing a proposal using a flexible function of the vote on each side of the discontinuity.[25] The probability of implementation increases almost monotonically in the vote share, but we observe a discrete jump at the majority threshold. Table 5 estimates the size of the jump at the discontinuity. Column 1 shows that for the whole sample, a proposal that passes has a 52.5% higher probability of being implemented than one that does not. This is an average estimate for all vote outcomes, whereas we seek to estimate whether the probability of implementation changes just around the discontinuity. To do so we replicate the analysis in Table 3 and estimate how passing a proposal changes the probability of implementation for increasingly small vote intervals around the majority threshold. Intuitively, passing should lead to a lower differential probability of implementation as we narrow the interval. However, around 1.5% of the majority threshold (Column 5), the differential

[25] In particular, we use an average kernel smoother with a bandwidth of approximately 20 observations.

probability of implementation is still quite high (45.8%) and statistically significant. Column 6 displays the full model given by equation (2) and estimated using a polynomial in the vote share of order three on each side of the threshold: We obtain a very similar coefficient of 52.5%, significant at the 5% significance level.

With this estimate of the probability of implementation in hand we can provide a back-of-the-envelope estimate of the value of a Say-on-Pay proposal. Using the abnormal returns from Table 3 of between 1.76% and 2.4%, and re-scaling by a probability of implementation around the threshold of 52.5%, the value of adopting a Say-on-Pay proposal is estimated to be about 3.4% to 4.6%.[26]

4.3. The effect of Say-on-Pay on firm outcomes

We have established that the market reaction to passing a Say-on-Pay provision is positive. This may reflect market perceptions of the potential cost-savings and managerial efficiency gains as a result of the Say-on-Pay provision. As described in Section 2, there are at least two channels by which Say-on-Pay can deliver better firm performance: first, through a stricter alignment of pay with performance; second, through more efficient monitoring and the risk of the CEO being dismissed if the vote does not pass. Given that a negative outcome on the subsequent Say-on-Pay votes sends a very negative signal, the CEO may change behavior out of concern for his/her career. In this section we evaluate the effects of Say-on-Pay proposals that may result from closer monitoring and better contractual incentives.

Tables 5 and 6 show the impact of passing a Say-on-Pay proposal on variables

[26] This re-scaling gives an approximation of the actual effect of implementation. It is equivalent to the point estimate of an IV regression. Although within our sample we cannot estimate the first stage of an IV regression with enough precision, we show in Table 5 that the jump in implementation is statistically different from zero. This is consistent with the previous governance literature that also finds that there is a jump in implementation at the majority threshold of non-binding shareholder proposals.

that capture firm profitability, long-term performance and other real outcomes. Each cell corresponds to a different regression that measures the effect of passing a proposal at the discontinuity. We again use the identification strategy given by equation (2) with third order polynomials on each side of the majority threshold. Each column corresponds to a different dependent variable y_{ft} and each panel to a different year-to-year effect.

We denote as year *t* the year in which the Say-on-Pay proposal is voted. Annual meetings are held between two fiscal year ends, which is when the variables used in this and the following sections are recorded.[27] Therefore we define the time periods such that there are at least six months between the annual meeting when the vote is held and fiscal year end *t*. This means that the change between *t* and *t* -1 includes some pre-treatment months and at least 6 of the first post-treatment months. The dependent variables in the first panel measure changes in the variables from *t-1* to *t*. In the second they measure changes from the end of the year of the vote *t* until the first full year after the Say-on-Pay vote (*t+1*). Variables are winsorized at the 5% level.

Table 6 reports the effect of passing a Say-on-Pay proposal on commonly used profitability measures. We define the dependent variables in this table as changes within the firm to identify the within-firm effect of Say-on-Pay. Overall, Table 6 shows that there are no significant effects of Say-on-Pay between *t-1* and *t*, but significant increases in profitability between *t* and *t+1.* More specifically, firms passing Say-on-Pay have $3.5 higher earnings per share, a 5.8% higher return on assets, and a 5.1% higher return on operating assets between *t* and *t+1*. All these effects are significant at 1% and economically quite large, which is consistent with the large market value effects found earlier. They also have higher Tobin's Q (0.13) and return on equity (0.11), although these are not significant at standard

[27] Most of the proxy season takes place between April and June - 88% of the proposals in our sample take place before June.

levels.

How is this better performance attained? In Table 7 we examine measures of firm strategy and performance beyond earnings to understand the mechanisms through which performance improves. Again, we find that there are few significant changes between *t-1* and *t* (only an increase in employment that is not sustained the following period), and that most of the significant improvement occurs between *t* and *t+1* (that is, between 6 and 18 months after the vote) and is sustained thereafter. The most striking result is that we find a 21.6% and highly significant higher increase in labor productivity (defined as the growth in sales per worker) in firms that pass Say-on-Pay between *t* and *t+1* (Column 1). Columns 2 and 3 find that this effect is driven both by a 6% decline in employment and an increase in 11% sales. Although the estimates for these variables are not significant at standard levels, their ratio is (column 1). Furthermore, in the same period capital expenditure and overheads (SG&A) drop significantly in firms that pass a Say-on-Pay vote. This suggests that the firm is more efficiently run, since (potentially superfluous) capital expenditure and costly overheads are reduced. In contrast, we found no significant changes in other firm policies such as leverage. Interestingly, total payout (dividend and share repurchases) grows by 1.8%, although this is not statistically significant at conventional levels.

In sum, CEOs and executives seem to be reacting the Say-on-Pay provision by delivering better earnings and returns to shareholders. This performance improvement is accompanied by better productivity ratios, a reduction in overheads, and lower rates of increases in capital expenditure. Say-on-Pay provisions seem to push CEOs to deliver stronger performance: they cut costs while increasing productivity. The economic magnitude of our estimates on performance is quite large, which suggests that the changes in behavior accompanying Say-on-Pay around the threshold are significant and consistent with the market value response, although we cannot rule out that some of these effects are short lived or the result of earnings manipulation. The effects identified arise mainly 6 to 18 months after the Say-on-Pay proposal is passed – unfortunately, we cannot analyze a longer time period because in 2011 all firms started being subjected to Say-on-Pay. Moreover, since these are local effects by design one must be cautious with extrapolation – whether we can expect such large effects to apply to firms outside our sample or far from the discontinuity. However, at the very least our results suggest that firms where proposals failed by a small margin would have benefited greatly from it passing.

4.4. The effect of Say-on-Pay on CEO compensation

The main objective of Say-on-Pay proposals is to improve the alignment of CEO incentives with firm objectives. In this section we examine whether passing a Say-on-Pay proposal has an impact on the level and on the incentive structure of CEO pay.

In Table 8 we report the effect of Say-on-Pay at the discontinuity threshold on changes in different elements of CEO compensation. We measure all the monetary variables in percentage growth rates, so that the effects we report can be interpreted as the differential growth in the variable between firms that approve or reject Say-on-Pay by a close margin. Column 1 reports the effect on total CEO compensation. Although the coefficients are negative, we do not observe a statistically significant change in the growth rates of CEO compensation in the two years following the passing of a Say-on-Pay proposal. Column 2 reports the effect of Say-on-Pay on the probability of CEO turnover. If Say-on-Pay proposals induce better shareholder monitoring, they may increase the probability of turnover. On the other hand, CEOs may respond by performing better, offsetting the increased monitoring and lowering the chance of being dismissed. The estimates for the effect on the probability of turnover are negative but not significant, so CEO exit is comparable between firms that pass Say-on-Pay and those that do not (one cannot accurately distinguish between voluntary and forced departures with the existing data).

Next we look into the changes on CEO compensation within firms that do not change their CEO. Column 3 reports a similar pattern to Column 1, and the estimates are again not statistically different from zero. Taken together, the results in Columns 1 to 3 show no significant effects of Say-on-Pay on total CEO compensation or turnover.

We now turn to the different components of CEO pay. Column 4 reports the impact of passing Say-on-Pay on changes in salary: the rate of increase in salary is 4.4% lower one year after the passing of the Say-on-Pay proposal. This is in line with the effort to reduce the amount of compensation that is not sensitive to performance. Column 5 reports the effect on increases in variable compensation (granting of stock, options and bonus) and shows no particular differential pattern between firms that pass Say-on-Pay proposals and those that do not. Columns 6 to 8 focus on options and stock. The results suggest a statistically insignificant decrease in the growth of the option portfolio (column 6), the stock portfolio (column 7) and the delta of the stock and option portfolio in the period (i.e. its sensitivity to firm value) immediately following the vote, followed by a significant increase in those three variables between t and $t+1$.[28] This suggests there is no clear reaction in one direction for these components following the Say-on-Pay vote. (Note that the increase in performance-pay sensitivity could be induced by higher grants of options and shares, or more 'mechanically' through changes in the share price of firms).

We also explicitly evaluate changes in the structure of pay. All dependent variables in Table 9 are calculated as the change in the share of each pay

[28] The total delta of the portfolio measures the change in the dollar value of the stock and option portfolio per dollar change in the value of the firm stock and is calculated following Core and Guay (1999).

component (stock awards, option awards, bonus, perks and deferred earnings) in total compensation (as measured in Execucomp by tdc1). In column 1, if anything, we see a decrease in the share of stock awards (a 9.1% decrease in the first period, significant at 10%, and a further 9% in the following period, although the latter is not significant). The share of option awards shows positive but not significant coefficients, casting some doubt on whether the results in Columns 6 and 8 of Table 8 reflect a conscious strategy of firms or simply a change in the value and option deltas of pre-existing option packages. There are no clear significant patterns with respect to bonus awards.

Finally, we find no effect in the share of compensation that is defined as perks and could be interpreted as private benefits (Column 4), nor in deferred compensation.

Overall, the results in this section show no systematic or sustained effects of Say-on-Pay on CEO compensation. Total pay does not change significantly (other than a small decline in salary), and the different components of compensation do not change in an identifiable and consistent manner. While some results might be suggestive of a shift from fixed pay to more variable pay (consistent with the stated objectives of most Say-on-Pay proposals) this conclusion is not robust across different measures. The absence of a significant effect on pay levels or pay structure can result from Say-on-Pay having no effect on pay, but could also be explained by adjustments in pay packages that are heterogeneous across firms. Even if there is room for improvement in CEO pay packages, the deviation from the optimal contract may vary across firms: If each firm responds in a different way or requires a different treatment, this would induce imprecise estimates of the average effect of Say-on-Pay.[29] In any case, we can rule out the notion that Say-on-Pay systematically curbs compensation across firms.

[29] Given our identification strategy, unfortunately the small sample size does not allow us for a thorough exploration of these heterogeneous effects.

5. Conclusion

Say-on-Pay gives shareholders a mechanism to express their voice, their view on how the firm is run and on whether CEO pay policies are aligned with performance. Therefore it may affect firm value through several channels: Say-on-Pay may affect firm performance through better designed pay structures that motivate CEOs; It also lowers the shareholder cost of expressing dissent, and therefore makes monitoring by shareholders more attractive and effective. Say-on-Pay can also have a negative effect on performance if it imposes large costs on firms.

We find that adopting Say-on-Pay can generate substantial value for shareholders. The use of a regression discontinuity design on the outcomes of shareholders proposals to adopt a Say-on-Pay policy allows us to deal with the presence of prior expectations in an event study setting, and to estimate the causal effect of adopting the policy. Say-on-Pay proposals that pass yield, on average, an abnormal return of 1.76% to 2.5% relative to those that fail on the day of the vote. We thus estimate the actual value of adopting a Say-on-Pay proposal to be around 4% of firm value, an economically sizeable effect that potentially arises through different channels.

We find that, in our sample of firms that were target of Say-on-pay proposals, firms that pass Say-on-Pay display stronger performance outcomes. CEOs seem to be reacting to having a Say-on-Pay provision in place by delivering better earnings per share, stronger profitability and higher Tobin's Q. We also find that Say-on-Pay leads to higher labor productivity and reductions in overheads and capital expenditure. In short, Say-on-Pay provisions appear to lead to more efficiency and stronger firm performance.

We find no effect of Say-on-Pay on total CEO compensation. In terms of pay composition, we find significant effects but these are contradictory and there is no systematic pattern. Despite this, we cannot rule out the idea that adjustments to pay packages may be heterogeneous across firms. Even if there is room for improvement in CEO pay packages, not all firms necessarily respond in the same way. If each firm requires a different treatment this would induce imprecise estimates of the effect of Say-on-Pay.

Our results suggest that Say-on-Pay is akin to an annual confidence vote in which shareholders approve or reject the CEO's performance relative to pay, that it empowers shareholders by offering a mechanism through which they can punish poor CEO performance, and that firms perform better as a result.

TABLE 1

Shareholder Say-on-Pay Proposals

This table displays the frequency of Say on Pay voted proposals, the percent of passed and the average support over time. Data is collected by Riskmetrics on all shareholders Say on Pay proposals from 2006 until 2010 for all S&P 1,500 companies plus an additional 500 widely held firms. For all of our observations the threshold to pass a proposal is 50%.

Shareholder Proposal Summary Statistics						
Year	**Voted Proposals**	**Passed Proposals**	**Percentage Passed Proposals**	**Average Vote Outcome**	**# -5, +5**	**# -10,+10**
2006	7	0	0%	40.11	0	5
2007	51	6	11.76%	40.9	13	31

Total	250	51	20.4%	43.33	88	168

TABLE 2

Descriptive Statistics

This table describes the Say on Pay sample of 250 voted proposals. All accounting variables are obtained from Compustat: Market Value (mkvalt_f), Tobin's Q is defined as the market value of assets (AT+mkvalt_f-CEQ) divided by the book value of assets (AT), and balance sheet Deferred Taxes and Investment Tax Credit (TXDITC), Return on Equity (NI/(CEQ+TXDITC)), Return on Assets (NI/AT), OROA (Cashflow/Total Assets), Leverage ((DLTT+DLC)/AT), Overheads (XSGA/XOPR), Total Payout ((DVT+PRSTKC)/AT), Sales per Worker (SALE/EMP), Number of Employees (EMP). CEO Pay is defined as TDC1 in Execucomp. Abnormal Pay is defined as the absolute deviation of pay residuals. Variable compensation is the sum of options and stock awards. Option portfolio is the Black-Scholes value of the options including reloads. Stock Portfolio is the total value of shares excluding options. Delta Portfolio is the delta for both the option and stock portfolios. Ownership variables are generated from Thomson 13F database. All monetary values are in 2010 US$. Note that the number of observations may change due to missing values in some of the variables.

TABLE 3

Abnormal Returns around the Majority Threshold

This table presents regressions of the abnormal returns on the day of the meeting t=0, on whether the Say-on-Pay proposal passed. Abnormal returns are computed using two benchmarks: market model and four factor model (Fama French and momentum factors; Carhart, 1997). Column 1 estimates are based on the whole sample. Column 2 restricts the sample to observations with a vote share within ten points of the threshold, column 3 to five points and so forth. Column 6 introduces a polynomial in the vote share of order 3, one on each side of the threshold, and uses the full sample. All columns include year dummies; standard errors (in parentheses) are clustered by firm. Significance at the 10%, 5%, and 1% levels are indicated by *, **, and *** respectively.

TABLE 4

Abnormal Returns beyond the Day of the Meeting

This table presents the effect of passing a Say-on-Pay proposal on abnormal returns around different event windows. Column 1 reports the effect of pass one day before the meeting. Column 2 reports the effect on the day of the meeting. Column 3, 4 and 5 report the effect of pass on the cumulative abnormal returns for two days, two weeks and six weeks respectively. Abnormal returns are computed using two benchmarks: market model and four factor model (Fama French and momentum factors; Carhart,1997). The specification is equation (2) and uses a polynomial in the vote share of order 3 on each side of the threshold. All columns include year dummies; standard errors (in parentheses) are clustered by firm. Significance at the 10%, 5%, and 1% levels are indicated by *, **, and *** respectively.

TABLE 6

Effect of Passing a Say-on-Pay Proposal on Firm Profitability

This table presents the effect of passing a Say-on-Pay proposal on firm profitability measures. We estimate the specification in equation (2) using a polynomial in the vote share of order 3 on each side of the threshold. The dependent variables are obtained from Compustat are all defined as within firm changes. Column 1 reports changes in Tobin's Q, defined as the market value of assets divided by the book value of assets ((AT-CEQ+mkvalt-txditc)/AT). Column 2, 3 and 4 report the change in Earnings per Share (EPS), Return on Equity (NI/(CEQ+TXDITC)) and Return on Assets (NI/AT), respectively. Column 5 reports the change in the Operating Return on Assets (CashFlow /AT). All dependent variables are winsorized at the 5th and 95th percentile. All columns include year dummies. Standard errors (in parentheses) are clustered by firm. Significance at the 10%, 5%, and 1% levels are indicated by *, **, and *** respectively.

TABLE 7

Real Effects of Passing Say-on-Pay Proposals

This table presents the effect of passing a Say-on-Pay proposal on firm outcomes. We estimate the specification in equation (2) using a polynomial in the vote share of order 3 on each side of the threshold. The dependent variables are obtained from Compustat are defined in growth terms or changes (depending on whether they are in levels or ratios). Column 1 reports the growth in labor productivity defined as sales per worker (SALE/EMP). Column 2 reports growth in Employment (EMP). Column 3 reports growth in Sales (SALE), Column 4 reports the change in Total Payout ((DVT+PRSTKC)/AT). Column 5 reports changes in the Capex ratio (Capex/AT). Column 6 reports the change in Overheads (XSGA/XOPR). Column 7 reports the growth in Total Assets (AT) and column 8 changes in the leverage ratio (DLTT+DLC/AT). All dependent variables are winsorized at the 5th and 95th percentile. All columns include year dummies. Standard errors (in parentheses) are clustered by firm. Significance at the 10%, 5%, and 1% levels is indicated by *, **, and *** respectively.

TABLE 8

Passing Say on Pay Proposals and Changes in the Level of Compensation

This table presents the effect of passing a Say-on-Pay proposal on compensation measures. We estimate the specification in equation (2) using a polynomial in the vote share of order 3 on each side of the threshold. The dependent variables are obtained from Execucomp. Column 1 reports growth in Total Compensation (TDC1), column 2 the change in CEO Turnover and column 3 growth in Total Compensation within CEO. Column 4 reports growth in Salary and column 5 growth in Variable Compensation (Stock_awards_fv+Option_awards_fv+Bonus+ Noneq_Incent). Column 6 and 7 report growth in Option and Stock Portfolio, respectively. Column 8 reports growth in Stock and Option Portfolio Delta. All dependent variables are winsorized at the 5th and 95th percentile. All columns control for year fixed effects. Standard errors (in parentheses) are clustered by firm. Significance at the 10%, 5%, and 1% levels is indicated by *, **, and *** respectively.

Appendix

TABLE A1

Sample Selection

This table compares the Say on Pay sample of 250 voted proposals with the SP1500 universe for the same years. As well, it compares the Say on Pay Close votes sample (within 10 percentage points) with the full Say on Pay sample. All accounting variables are obtained from Compustat: Market Value (mkvalt_f), Tobin's Q is defined as the market value of assets (AT+mkvalt_f-CEQ) divided by the book value of assets (AT), and balance sheet Deferred Taxes and Investment Tax Credit (TXDITC), Return on Equity (NI/(CEQ+TXDITC)), Return on Assets (NI/AT), OROA (Cashflow/Total Assets), Leverage ((DLTT+DLC)/AT), Overheads (XSGA/XOPR), Total Payout ((DVT+PRSTKC)/AT), Sales per Worker (SALE/EMP), Number of Employees (EMP). CEO Pay is defined as TDC1 in Execucomp. Abnormal Pay is defined as the absolute deviaton of pay residuals. Onwership variables are generated from Thomson 13F database. All monetary values are in 2010 US$. Note that the number of observations may change due to missing values in some of the variables.

TABLE A2

Pre-differences in Firm Characteristics as a Function of the Vote Outcome

Table A2 tests whether passing a Say-on-Pay vote on the meeting date is systematically related to firm characteristics prior to the meeting. Note that in Panel A t refers to days, while for the rest, t refers to years. Each row corresponds to a different dependent variable and each entry comes from a separate regression. Each entry in the table reports the coefficient on whether a proposal passed. Columns 1 and 2 (3 and 4) report the estimated effect of passing a vote on outcome variable levels (changes) the year before the annual meeting, t-1 (between t-2 and t-1). Columns 1 and 3 present estimates without controlling for a polynomial in the vote share and, therefore, estimate the average effect of passing relative to not passing. Columns 2 and 4 include the polynomial in the vote share of order 3 on each side of the threshold such that it effectively estimates the effect at the discontinuity. All columns control for year fixed effects and standard errors (in parenthesis) are clustered at the firm level. Significance at the 10%, 5%, and 1% levels are indicated by *, **, and *** respectively.

Polynomial in the vote share	no	yes	no	yes

In Table A2 we examine whether there are any pre-existing differences at the majority threshold between firms that pass a Say-on-Pay proposal and firms that don't. Columns 1 and 3 compare the characteristics of the whole population of firms, while columns 2 and 4 report only the effect at the discontinuity by including polynomials of order three on either side of the threshold. Columns 1 and 2 refer to the variables in levels and 3 and 4 in growth rates.

Column 1 shows that, on average, firms that pass the proposal have different characteristics from those where the proposal fails. For instance, firms where the proposal is passed have on average lower prior return on assets than those where it fails. These are the kind of selection problems that would make the estimates of a standard OLS regression biased. In contrast, when we control for a polynomial in the vote share and estimate the effect at the discontinuity (in column 2 and 4), we find that these average differences across firms on each side of the threshold disappear. We do find some differences in the level of overheads and the growth rates of option grants although given the number of coefficients that we check it is expected that some of them would seem statistically different even if both samples are drawn from the same distribution.

In general, we do not find any systematic differences between firms on each side of the majority threshold.

TABLE A3

Abnormal Returns Controlling for Other Proposals

Abnormal returns are computed using two benchmarks: a market model (in Columns 1 and 2) and a four factor model (Fama French and momentum factors; Carhart,1997) (in Columns 3 and 4). Columns 1 and 3 include as controls the vote outcome of other proposals in the same meeting, third order vote polynomials to each side of the discontinuity different for SoP votes and other votes and year dummies. Columns 2 and 4 include a dynamic specification and firm fixed effects, similar to Cuñat, Gine and Guadalupe (2012). The sample includes all votes from 2006 until June 2010. We drop observations outside the top (bottom) 1% of abnormal returns of the full sample. All columns control for year fixed effects and standard errors (in parenthesis) are clustered at the firm level. Significance at the 10%, 5%, and 1% levels are indicated by *, **, and *** respectively.

	(1)	(2)	(3)	(4)
	Market Model		**Fama French & Momentum**	
Say on Pay Proposals				
Day of the vote, *t*	0.021**	0.027***	0.014*	0.018*
	(0.009)	(0.010)	(0.008)	(0.010)
One day later, *t+1*		0.010		0.007
		(0.010)		(0.010)
Days *t+2* to *t+9*		-0.018		-0.013
		(0.024)		(0.021)

Day of the vote, *t*	0.006**	0.008**	0.004	0.006
	(0.003)	(0.004)	(0.003)	(0.004)
One day later, *t+1*		0.004		0.001
		(0.006)		(0.005)
Days *t+2* to *t+9*		0.020		0.016
		(0.013)		(0.011)
Observations	1,024	5,120	1,024	5,120
R-squared	0.044	0.025	0.034	0.012
Number of firms	517	517	517	517

The specification in columns (1) and (3) builds on the main specification in this paper (equation (2)) to control for the average effect of all other governance proposals voted in the annual meeting by adding a second RD structure to the specification that is identical in structure to the one used for Say-on-Pay proposals. The specification uses the universe of governance-related shareholder proposals in firms that hold a Say-on-Pay vote. We split them into Say-on-Pay proposals and other proposals and estimate:

$$y_{ft} = D^{A}{}_{ft}\theta^{A} + P^{A}{}_{r}(v^{A}{}_{ft}, \gamma^{Ar}) + P^{A}{}_{l}(v^{A}{}_{ft}, \gamma^{Al}) + D^{B}{}_{ft}\theta^{B} + P^{B}{}_{r}(v^{B}{}_{ft}, \gamma^{Br}) + P^{B}{}_{l}(v^{B}{}_{ft}, \gamma^{Bl}) + \alpha_{\tau} + u_{ft}$$

Where the superindex A refers to Say-on-Pay proposals and B refers to other governance proposals. The reported coefficients are θ^{A} and θ^{B} . Whenever there is more than one B type proposal in a given meeting, we aggregate them (and their vote shares) linearly, using the same method as in Cuñat, Giné and Guadalupe (2012).

Columns (2) and (4), additionally, allow for the possibility of dynamic effects and interactions between the abnormal returns at different time horizons. Following Cellini, Ferreira, and Rothstein (2010) we pool the abnormal returns at different time horizons and estimate the following regression.

$$y_{ft+T} = D^{A}{}_{ft+T}\theta^{AT} + P^{A}{}_{r}(v^{A}{}_{ft}, \gamma^{Ar}{}_{T}) + P^{A}{}_{l}(v^{A}{}_{ft}, \gamma^{Al}{}_{T}) + D^{B}{}_{ft+T}\theta^{BT} + \ldots$$
$$\ldots + P^{B}{}_{r}(v^{B}{}_{ft}, \gamma^{Br}{}_{T}) + P^{B}{}_{l}(v^{B}{}_{ft}, \gamma^{Bl}{}_{T}) + \lambda_{fT} + \alpha_{\tau} + u_{ftT}$$

Where the polynomials are allowed to vary at different horizons "T" and a dummy for the distance to the date of the vote (λ_{fT}) is added.

The methodology of this table closely follows Cuñat, Giné and Guadalupe (2012) and more details can be found in its section IIB.

Figure A4
Vote Distribution and Expected Abnormal Returns.

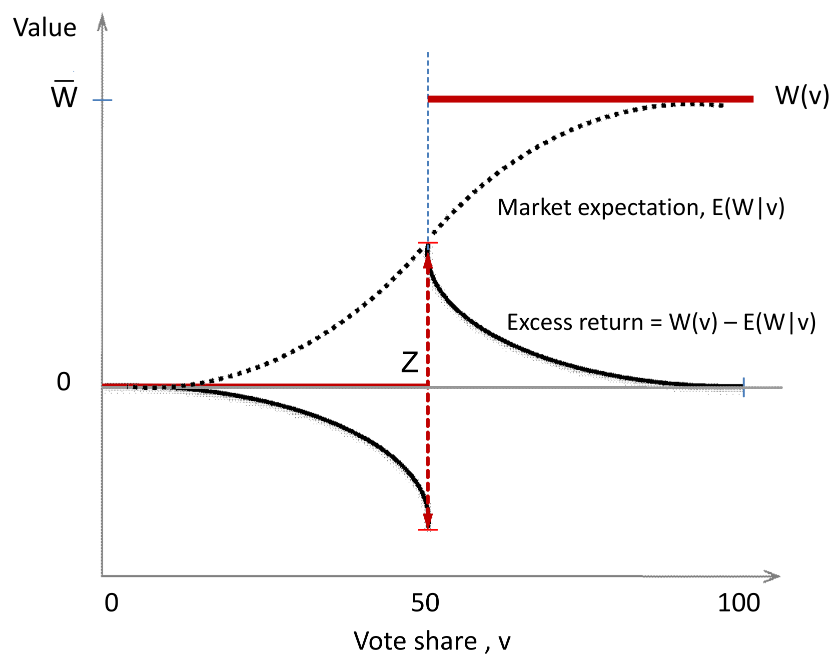

Figure A4 illustrates how one can recover the effect of passing a proposal on abnormal returns using a regression discontinuity. The figure uses 50% as the relevant majority threshold for all firms. The example assumes that the implementation of the proposal is binding; although extending the analysis to non-binding fuzzy discontinuity design is straightforward. Our identification strategy only requires that there is a discrete jump in the probability of implementation at the majority threshold (this is the "fuzzy" regression discontinuity setting as in Lee and Lemieux, 2010).

Suppose that the value of implementing a proposal is $\overline{W}$, that the majority threshold is 50% and that passing a proposal is binding (firms have to adopt it).[30] The step function W(v) represents the change in firm value as a function of the actual vote. Prior to the vote, the market has formed an expectation of the outcome of the vote and incorporated its expected impact on firm value into stock prices, E(w| v). This expectation is a smooth version of the previous step function. The abnormal

[30] Extending the analysis to non-binding proposals is straightforward. Our identification strategy only requires that there is a discrete jump in the probability of implementation at the majority threshold (this is the "fuzzy" regression discontinuity setting as in Lee and Lemieux, 2010).

return that we observe after the vote is the difference between the actual value of the proposal to the firm W(v) (which is either W or zero, depending on whether it passes) and its expected value before the vote E(W|v).

One can recover the value of the proposal by fitting two flexible functions of the vote to each side of the discontinuity and allowing for a discrete jump at the discontinuity. The combination of an event study with a regression discontinuity design solves the pervasive problem of assessing prior expectations in an event study. The value Z captures $(W(v)_r - E_r(W(v)|v)) - (W(v)_l - E_l(W(v)|v))$. Where $W(v)_r = \overline{W}$, $W(v)_l = 0$, $E_l(W|v)$ denotes the expected effect of the vote as the vote approaches 50 from the left and similarly $E_r(W|v)$ when the vote approaches 50 from the right. As long as prior expectations are the same to each side of the discontinuity (i.e. E(W(v)|v)) is continuous), their effect cancels out in the RD design.
